Acute graft rejection is an important clinical problem in renal transplantation and an adverse predictor for long term graft survival. Plasma biomarkers may offer an important option for post-transplant monitoring and permit timely and effective therapeutic intervention to minimize graft damage. This case-control discovery study ( $n = 32$ ) used isobaric tagging for relative and absolute protein quantification (iTRAQ) technology to quantify plasma protein relative concentrations in precise cohorts of patients with and without biopsy-confirmed acute rejection (BCAR). Plasma samples were depleted of the 14 most abundant plasma proteins to enhance detection sensitivity. A total of 18 plasma proteins that encompassed processes related to inflammation, complement activation, blood coagulation, and wound repair exhibited significantly different relative concentrations between patient cohorts with and without BCAR ( $p$  value  $< 0.05$ ). Twelve proteins with a fold-change  $\geq 1.15$  were selected for diagnostic purposes: seven were increased (fibrinogen, lipopolysaccharide-binding protein, peptidase inhibitor 16, complement factor D, mannose-binding lectin, protein Z-dependent protease and  $\beta_2$ -microglobulin) and five were decreased (kininogen-1, afamin, serine protease inhibitor, phosphatidylcholine-sterol acyltransferase, and sex hormone-binding globulin) in patients with BCAR. The first three principal components of these proteins showed clear separation of cohorts with and without BCAR. Performance improved with the inclusion of sequential proteins, reaching a primary asymptote after the first three (fibrinogen, kininogen-1, and lipopolysaccharide-binding protein). Longitudinal monitoring over the first 3 months post-transplant based on ratios of these three proteins showed clear discrimination between the two patient cohorts at time of rejection. The score then declined to baseline following treatment and resolution of the rejection episode and remained comparable between cases and controls throughout the period of quiescent follow-up. Results were validated using ELISA where possible, and initial cross-validation estimated a sensitivity of 80% and specificity of 90% for classification of BCAR based on a four-protein ELISA classifier. This study provides evidence that protein concentrations in plasma may provide a relevant measure for the occurrence of BCAR and offers a potential tool for immunologic monitoring. *Molecular & Cellular Proteomics* 9:1054–1067, 2010.

Although advances in immunosuppression have increased the success of renal transplantation continuously during the past decades, immunological injury to the graft remains a critical barrier to long term survival (1–4). Both innate and immune responses are implicated in the process of graft rejection (5–7). Major and minor histocompatibility antigens expressed on graft tissue are quickly identified following implantation through direct or indirect pathways of the innate response, and consequent activation of T-cell and B-cell components of the host adaptive immune response leads to cellular and antibody-mediated injury to numerous structural components of the grafted organ (8). The resulting inflammatory sequence comprising cellular infiltration, antibody production, complement deposition, and activation of the coagulation cascade can be identified by histological changes on allograft biopsy (biopsy-con-

# COPD Biomarker Program

- **Problem:** 50-80% of COPD patients are under-diagnosed
  - The current functional biomarker, FEV1, is insensitive
  - Lack of surrogate endpoints inhibit development of new therapies
- **Goal:** Using a non-targeted biomarker discovery approach, identify novel blood-based biomarkers to...
  - Risk-stratify patients for **exacerbations**
  - Develop and qualify new compounds and drugs for the treatment of patients with COPD
- **Cohort:** GlaxoSmithKline ECLIPSE Cohort (~2600 COPD patients and controls)
- **Outcomes:**
  - Simple, early and accurate diagnosis of COPD to allow for effective treatment and earlier management of the disease
  - Screening tool or surrogate marker to shorten clinical trials or create a new drug target
